Cancer will affect 1 in 3

- 25% of cancers run in families (inherited).
- 75% of cancers are sporadic, i.e. anyone can get it.
- Every year, 1.3 million Americans will be diagnosed with cancer, and 550,000 will die from cancer.

Germline vs. Sporadic Cancer

a. Germline (inherited) cancer

b. Sporadic cancer

Mutations observed in Colon Tumors

Challenges:

1. **Stromal contamination:**
Mutation may be present
in only 15%-25% of DNA.
2. Multiple, and closely spaced
mutations in multiple genes.
3. For early detection, need
to find one mutant in 100
wild-type.

Comparison of Arrays for Identifying Mutations

Hybridization Arrays:

- Discrimination based on match vs. mismatch hybridization; probes are very similar in sequence.
- T_m (melting temperature) of probes depend on target; considerable variation.

Universal Arrays:

- Discrimination based on match vs. mismatch ligation.
- Capture probes designed to have distinct sequences with no cross-hybridization.

Identifying Mutations by Hybridization: 1

Target: 5'-CATTAAGAAAATATCATCTTTGGTGTTCCTATCATCA

Probes:

3' - TTTATAXTAGAAACC (SEQ. ID NO:9)

3' - TTATAGXAGAAACCA (SEQ. ID NO:10)

3' - TATAGTXGAAACCAC (SEQ. ID NO:11)

3' - ATAGTAXAAACCACA (SEQ. ID NO:12)

3' - TAGTAGXAACCACAA (SEQ. ID NO:13)

3' - AGTAGAXACCACAAA (SEQ. ID NO:14)

3' - GTAGAAXCACAAAG (SEQ. ID NO:15)

3' - TAGAAAXCACAAAGG (SEQ. ID NO:16)

3' - AGAAACXACAAAGGA (SEQ. ID NO:17)

Identifying Mutations by Hybridization: 2

Target: 5' - CATTAAAGAAATAATCATCTTTGGTGTTCCTATGATGA

Probes:

3' - TTTATACTAGAAACC (SEQ. ID NO: 9C)
3' - TTTATACTAGAAACC (SEQ. ID NO: 9A)
3' - TTTATACTAGAAACC (SEQ. ID NO: 9T)
3' - TTTATACTAGAAACC (SEQ. ID NO: 9C)

3' - TTATAGCTAGAAACCA (SEQ. ID NO: 10T)
3' - TTATAGCTAGAAACCA (SEQ. ID NO: 10C)
3' - TTATAGCTAGAAACCA (SEQ. ID NO: 10G)
3' - TTATAGCTAGAAACCA (SEQ. ID NO: 10A)

3' - TATAGTCTGAAACCAC (SEQ. ID NO: 11A)
3' - TATAGTCTGAAACCAC (SEQ. ID NO: 11T)
3' - TATAGTCTGAAACCAC (SEQ. ID NO: 11C)
3' - TATAGTCTGAAACCAC (SEQ. ID NO: 11G)

Identifying Mutations by Hybridization: 3

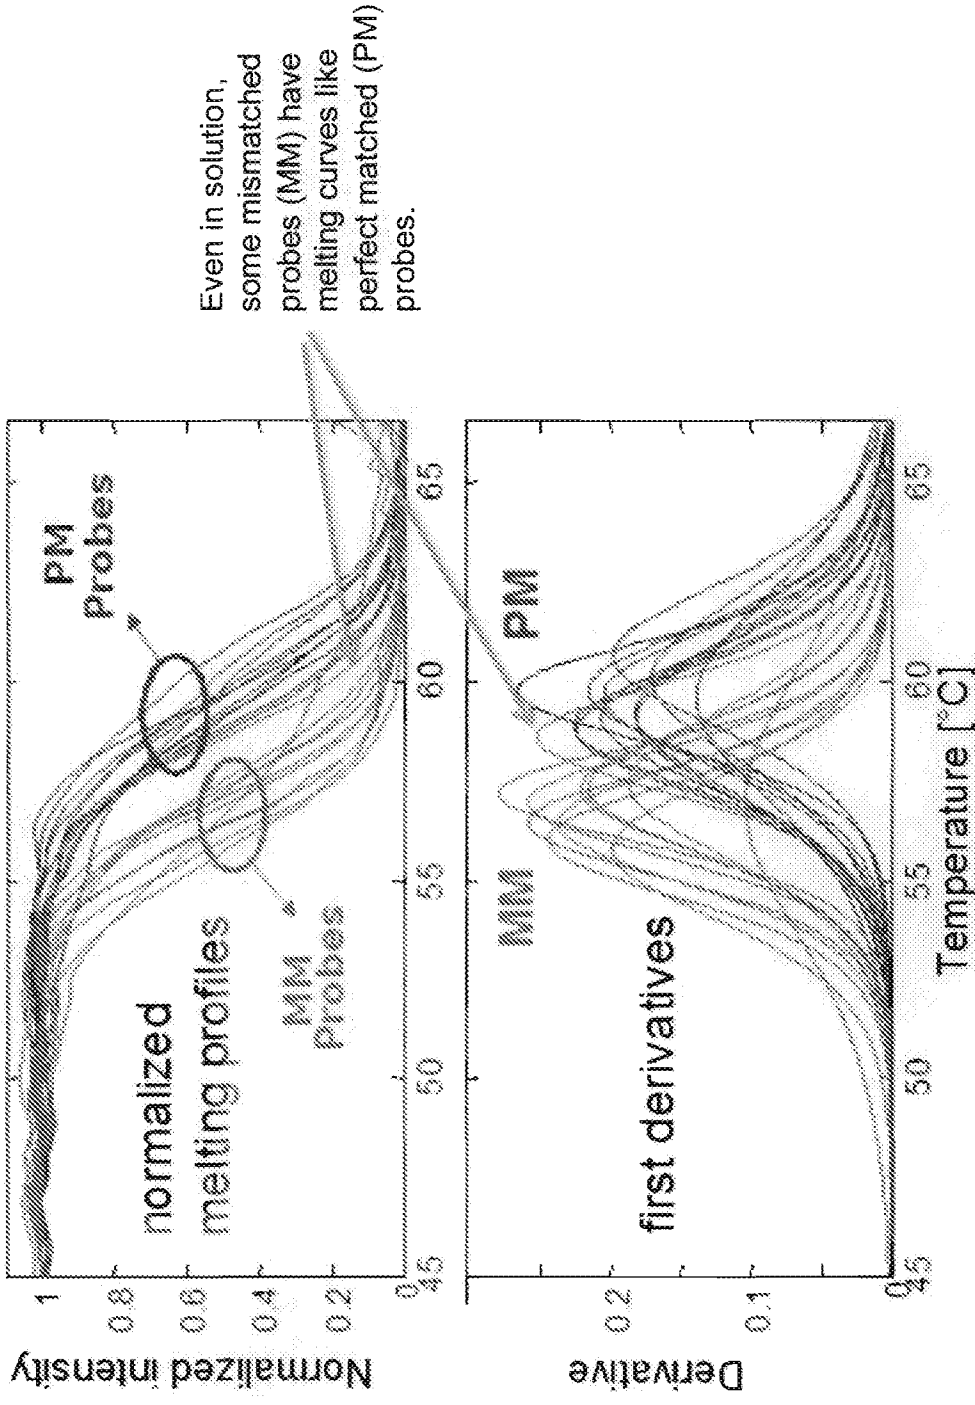

Target: 5'-CATTAAGAAATAATCATCTTTGGTGTTCCTATGATGA	Probes:
Probes: 3'-TTTATACTAGAAACC (SEQ. ID NO:9G)	93%
3'-TTTATACTAGAAACC (SEQ. ID NO:9A)	Identical
3'-TTTATACTAGAAACC (SEQ. ID NO:9T)	
3'-TTTATACTAGAAACC (SEQ. ID NO:9C)	87%
Target: 5'-CATTAAGAAATAATCATCTTTGGTGTTCCTATGATGA	Identical
3'-TTTATACTAGAAACC (SEQ. ID NO:10T)	
3'-TTTATAGCAGAAACCA (SEQ. ID NO:10C)	
Target: 5'-CATTAAGAAATAATCATCTTTGGTGTTCCTATGATGA	
3'-TTTATAGCAGAAACCA (SEQ. ID NO:10G)	93%
3'-TTTATAGCAGAAACCA (SEQ. ID NO:10A)	Identical

Oligonucleotide microarrays: widely applied-- poorly understood.

Microarray technology, which has been around for almost two decades, now provides an indispensable service to the biomedical research community. Soaring demand for high-throughput screening of genes potentially associated with cancer and other diseases..., have substantially opened up the application of this technology to many fields of science. Yet, despite this significant progress, the fundamental understanding of the pillars of this technology, have been largely unexplored, in particular for oligonucleotide-based microarrays. In fact, most of the current approaches for the design of microarrays are based on 'common-sense' parameters, such as guanine- cytosine content, secondary structure, melting temperature or possibility of minimizing the effects of nonspecific hybridization. However, recent experiments suggest that these are inadequate. Here we discuss these results, which challenge the basic principles and assumptions of oligonucleotide microarray technology. It is clear that more systematic physicochemical studies will be required to better understand the hybridization and dissociation behavior of oligonucleotides.

Brief Funct Genomic Proteomic. 2007 Jun;6(2):141-8.

“Normalized” Melting Profiles of oligonucleotides in solution

Impact of point-mutations on the hybridization affinity of surface-bound DNA/ DNA and RNA/DNA oligonucleotide-duplexes: comparison of single base mismatches and base bulges.

Direct comparison of single base mismatches, insertions and deletions. The 16 mer probe sequence motif 3'- TTGACTTTCGTTTCTG-5' is complementary to the target BEI. Hybridization signals (data processing: raw fluorescence intensities; solution-background correction) of single base mismatch probes with substituent bases A (red crosses), C (green circles), G (blue stars), T (cyan triangles), running average of mismatch intensities (black line); perfect match probe signals (grey symbols) single base insertion probes (solid lines) with insertion bases A (red), C (green), G (blue), T (cyan). Hybridization signals of single base deletions (orange dashed line) are comparable to that of mismatches at the same position. Increased hybridization signals of certain insertion defects are due to positional degeneracy of base bulges (see discussion).

Position dependent mismatch discrimination on DNA microarrays - experiments and model.

Fluorescence micrograph (taken with an Olympus IX81 epi-fluorescence microscope and a Hamamatsu EM-CCD camera) of a microarray feature-block comprising variations of the 16 mer probe sequence motif 3'-TATTACTGGACCTGAC-5'. Microarray hybridization was performed with the 5'-Cy3-labeled RNA oligonucleotide target 3'-AACUCGCUAAUAGACCUGGACUG-5' (target concentration: 1 nM in 5 x SSPE, pH 7.4, 0.01% Tween-20, T = 30°C). Each 3 x 3 sub-array comprises (randomly arranged) one perfect matching probe, three single base mismatch probes, four insertion probes and one single base deletion probe. In Fig. 2A the hybridization signals (fluorescence intensities, averaged over the center of the microarray features) are plotted versus the defect position. The size of each microarray feature is 21 μm and the pitch of the array is 35 μm . The significantly brighter feature-block at left comprises variations of the 20 mer probe sequence motif 3'-TTGAGCGGATATTACTGGACC-5'.

Position dependent mismatch discrimination on DNA microarrays - experiments and model.

Comparison of simulation results with the experimentally determined hybridization affinities for two probe sequence motifs (A) and (B). The four small sub-figures in the top section (from top left to bottom right) show the partition function Z and the duplex binding constant K as a function of defect position x (semi-logarithmic plots), the NN-free energies Δg° of particular NN-pairs as a function of NN-pair position xNN , and the statistical weight for complete duplex dissociation wD as a function of defect position. Irregularities in $Z(x)$ at the duplex ends are an artifact caused by the fact that only a single NN-pair is affected by a MM-base pair at the duplex end. The middle sub-figure shows the base pair opening probabilities (the fraction of strands in which the corresponding base pair at position xBP is unzipped) as a function of the defect position. The spectrum of differently colored curves encodes the different defect positions xMM (red – defect at left end; purple – defect at right duplex end). The bottom sub-figure compares the experimentally determined MM defect profile (mismatched base: A (red cross), C (green circle), G (blue star), T (cyan triangle); gray symbols correspond to PM probes) with the simulated MM defect profile $\theta(x)$ (dashed orange line). With $\Delta g_{def} = 1$ kcal/mol (at the simulation temperature of 325 K) and an error rate of 12 percent (per synthesis step) the calculated defect profile $\theta(x)$ matches well the experimental data.

Xba 240 SNP array analysis of CRC sample C0194A

► Testing the genotype for SNP_A-1713319

► Probesets designed for:

tatgttacatcagttactcctttca[**A/G**]tatagattaggttttaagtcctcc

← 25-mer tiled probes

► No. of 25-mer probes used : (5 fs + 5 rs) X 4 (i.e. quartet for PA, PB, MA, MB) = 40

► PA = perfect match for A; PB = perfect match for B ; MA = mismatch for A; MB = mismatch for B

► GTYPE call: "BB" = GG (homozygous guanine)

Xba 240 SNP array analysis of CRC sample C0194A

► Testing the genotype for SNP_A-1646260

► Probesets designed for:

tactgtaaggctgacacactgtat[AT]ataaacccggttttatctggcag

← 25-mer tiled probes

► No. of 25-mer probes used : (5 fs + 5 rs) X 4 (i.e. quartet for PA, PB, MA, MB) = 40

► PA = perfect match for A; PB = perfect match for B ; MA = mismatch for A; MB = mismatch for B

► GTYPE call: "AB" = AT (heterozygous adenine/thymine)

Disadvantages of Hybridization Arrays for Detecting Mutations

- Large variation in sequence context and probe T_m make it impossible to distinguish all mutations under uniform hybridization conditions.
- Normal DNA will sometimes hybridize to mutant probe sequence as well as the normal probe sequence, leading to false positives.
- Probes miss small deletions or insertions, leading to false negatives.
- Hybridization arrays cannot distinguish mismatch hybridization of normal DNA to mutant probe – resulting in 25%-50% signal – from match hybridization of mutant DNA, present at 25%-50% of the sample. This lack the sensitivity required to identify cancer mutations in the presence of stromal cells, leads to false negatives.

Grace's Family History:

1. Grandfather died at 30 (Rare Sarcoma).
2. Aunt died at 20. (Brain tumor)
3. Mother survived breast cancer at 22.

Does Grace carry a p53 mutation?

PCR / PCR / LDR / Universal Array

1. PCR amplify all p53 exons using gene-specific/universal primers and Taq polymerase. ♦

2. PCR amplify all primary products using universal primers and Taq polymerase. ♦

3. Perform LDR using mutation-specific LDR primers, common primers containing complementary zip code sequences, and thermostable ligase. ●

4. Capture fluorescent products on addressable array and score for presence of mutation.

Universal DNA array detection of small insertions and deletions in BRCA1 and BRCA2

LDR detection of three specific mutations in BRCA1 and BRCA2 on an addressable universal microarray. The diagram at upper left shows the assignment of each control and mutant sequence to specific addresses on the array surface. Control signals are directed to the upper three addresses; mutant signals are assigned to the lower three. The upper right image shows signal produced by a wild-type DNA. Left panel: representative hybridizations for individual DNA samples. Right panel: representative hybridizations for each mutation using pooled samples of DNA from Ashkenazi individuals. The mutations are identified on the extreme right.

Comparison of Array Hybridization Results When Mutations are Closely Spaced

Hybridization capture probes are complementary to unlabeled primer

Results: Incorrect Signals due to Cross-Hybridization

Hybridization capture Probes are Zipcodes

Results: Only Correct Signal at Each Zipcode

Advantage of Universal Arrays

1. Provide single array design to detect all target nucleic acid differences under uniform hybridization conditions.
2. Distinguish closely spaced and overlapping mutations, including small insertions and deletions.
3. Identify low abundance mutations for early detection of cancer.
4. Identify promoter methylation silencing of tumor suppressor genes. Helps predict outcome and guide cancer treatment.
5. Identify and quantify splice site changes.
6. Quantify RNA levels for gene expression profiling.
7. Determine DNA copy level changes, loss of heterozygosity (LOH), and SNPs for genome-wide association studies. Helps predict outcome and guide cancer treatment.

Advantage of Universal Arrays over Hybridization Arrays

Hybridization Arrays:

- Discrimination based on match vs. mismatch hybridization; probes are very similar in sequence.
- Cross-hybridization between perfect match and mismatch probes leads to false-positives and false-negatives.

Universal Arrays:

- Capture-specific probe sequences designed to differ by 25% or more to minimize cross-hybridization.
- Composite probes or products containing a target-specific portion and a capture-specific portion allow for accurate target identification.
